1 Functions

Definition 1.1. A function f from a set A to a set B, denoted as $f: A \to B$, associates to each $a \in A$ an element $f(a) \in B$. The set A is called the **domain** of f and the set B is called the **codomain** of f. We let Dom(f) denote the domain of f and Cod(f) denote the codomain of f.

Definition 1.2. The **range** of a real-valued function f, denoted Rng(f), is the set of values that f outputs; that is,

```
\operatorname{Rng}(f) = \{ y \in \mathbb{R} \mid y = f(x) \text{ for some } x \in \operatorname{Dom}(f) \} = \{ f(x) \mid x \in \operatorname{Dom}(f) \}
```

Definition 1.3. Let f be a real-valued function. A real-valued function g is called an **inverse** of f if f(g(x)) = x for all $x \in \text{Dom}(g)$ and g(f(x)) = x for all $x \in \text{Dom}(f)$. We denote this by $g = f^{-1}$.

Proposition 1.3.1. If g is an inverse of f, or in other words $g = f^{-1}$, then Dom(f) = Rng(g) and Dom(g) = Rng(f).

```
g(f(x)) = x for all x \in \text{Dom}(f) \implies x \in \text{Rng}(g), so \text{Dom}(f) \subseteq \text{Rng}(g).
If y \in \text{Rng}(g), then y = g(x) for some x \in \text{Dom}(g), thus f(y) = f(g(x)) = x
Since y \in \text{Dom}(f), \text{Rng}(g) \subseteq \text{Dom}(f)
```

By combining those two inclusions, we get Dom(f) = Rng(g). By symmetry of the definition of inverse functions, Dom(g) = Rng(f)

Proposition 1.3.2. Show that the inverse of a function is unique.

Let g and h be inverses of f. By the above propostion, $\operatorname{Dom}(g) = \operatorname{Rng}(f) = \operatorname{Dom}(h)$ Since $x \in \operatorname{Rng}(f)$, there is some $y \in \operatorname{Dom}(f)$ such that f(y) = xBut then g(x) = g(f(y)) = y = h(f(y)) = h(x)Therefore g(x) = h(x)

Definition 1.4. Let f be a function and $A \subseteq Dom(f)$. The **image** of A under f, denoted f(A), is

$$f(A) = \{ y \in \operatorname{Cod}(f) \mid y = f(x) \text{ for some } x \in A \}$$

Let $B \in \text{Cod}(f)$. The **preimage** of B under f, denoted $f^{-1}(B)$, is

$$f^{-1}(B) = \{x \in \text{Dom}(f) \mid f(x) \in B\}$$
